Bosma, Mark
Document World v3n2 PP: 19-27 Apr/May 1998
ISSN: 1025-9228 JRNL CODE: DCMW
WORD COUNT: 3722

...TEXT: them, an object server to store the files and a library server to
store the **indexes**. All popular scanner brands can be used to capture
information, and users can import different office **application** file
formats. A special **module** must be obtained for OCR, ICR, bar code
scanning and batch processing for high volume scanning, and another one is
required to integrate faxes. Documents can be stored on different **media**
and on different servers at different locations so it is a fully scalable
solution.

...SPECIFICATION requested by SisCSFilesToBackUpForLink, described below.
If countOfCommonStoreFilesToBackUp is zero, then commonStoreFilesToBackUp may be a NULL **pointer** and should be ignored by the **backup application** 118.

The return value is TRUE if the call succeeded, and FALSE otherwise. If FALSE...

...underscore)REPARSE(underscore)TAG(underscore)SIS. For each SIS link to be backed up, the **backup application** 118 should call (only once per link file) SisCSFilesToBackUpForLink.

The SisCSFilesToBackUpForLink function takes as input a **pointer** to the contents of the SIS reparse point for a link file that the **backup application** 118 is planning to store on the backup storage medium 122. This function also takes the length of the reparse data as a parameter, as well as an optional context **pointer** that is provided by the **backup application** and uninterpreted by the SIS DLL 116.

In accordance with one aspect of the present...of FIG. 13B first zeros the count of files to return and sets the array **pointer** to NULL, whereby the **backup application** 118 will not receive a common store filename unless needed. To this end, step 1322...

...returned status, and adds its filename string to the array for returning to the backup **application** . At step 1326 the countOfCommonStoreFilesToBackUp and commonStoreFilesToBackUp are appropriately adjusted, after which step 1328 returns the array (i.e., its **pointer**) and count to the **backup application** 118. Note that multiple common store files corresponding to a link file may be handled ...store file is already present on the volume, and if so, exits (returns a NULL **pointer** and a zero count) without returning the filename thereof to the restore **application program** 120. Note that if present on the volume, the common store file identifier will have...

...SPECIFICATION Agent 108, as part of the migration process of backup data files from (back slash) **BACKUP** (back slash)USERS 121 to (back slash) **BACKUP** (back slash)SYSTEM 122, builds a special **Index** Range Lookup file (e.g., 151 of FIGURE 3). This file, which is redundant in the sense than it can always be re-built from the contents of the **backup** data and directory files, includes a table which maps **index** ranges into **backup** data file names and which is arranged for a fast binary search. With the appropriate **backup** data file identified, this file is opened, and the **pointer** 162 to the FileInfoPtrs sections is read from the Header 160. The index range record...of the consolidation operation may also have to be deferred until no users have a **backup** set mounted that contains a reference to the file(s) in questions, Observe that the use of **indices** (instead of direct pointers) both for file and directory references greatly simplifies such an operation...

English Abstract

The invention is a **modular backup and retrieval** system. The **software** modules making up the backup and retrieval system run independently, and can run either on the same computing **devices** or on different computing **devices**. The modular **software** system coordinates and performs backups of various computing **devices** communicating to the modules. Actions of modules on one of the computing **devices** acts as a system manager for a network backup regimen. A management component acts as a manager for the archival and restoration of the computing **devices** on the network. It manages and allocates library **media** usage, maintains backup scheduling and levels, and supervises or maintains the **archives** themselves through pruning or aging policies. The management component is not hard wired in its functionality, but may adapt to changing circumstances in these policies. A second **software** module acts as a manager for each particular library **media**. A **media** component supervises the actual **media** to which the backups are made and the retrievals are pulled from. The **media** component provides an indexing function which serves to specifically locate any **data** and/or files **archived**, as well as other administrative details about the **data**. This indexing **information** is made available to the management component for easier processing.

Detailed Description

TITLE: **MODULAR BACKUP AND RETRIEVAL SYSTEM**
SPECIFICATION

CROSS-REFERENCE TO RELATED APPLICATIONS

The present **application** claims priority to U.S. Patent **Application** Serial No.

09/354,063, entitled "**Modular Backup and Retrieval System**,"
(Attorney Docket No.

044463.0013), filed July 15, 1999.

BACKGROUND

1. Technical Field
The...

...is directed to storage and retrieval systems. In particular, the invention is directed towards a **modular storage and retrieval** system for a computer or a series of interconnected computers.

2. Related Art
Conventional backup...

...wide backup and retrieval manager for the computing devices it is in contact with.

The **backup and retrieval** system may also take the form where the second **software** agent creates an **index** of information on the location of archived data during the course of creating an...

...library media. Thus, the location of the archived data is preserved,
3
and the second **software** agent communicates at least part of the **indexed** information to the first **software** agent. Also, the library media can comprise a plurality of different types of archival media...

...4

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a schematic block diagram of a **modular network backup** system according to the invention.

Fig. 2 is a logical block diagram of the various...

...take.

Fig. 3 is a logical block diagram of the various possible interconnections between the **modular** portions of the **backup** system of Fig. 1.

Fig. 4 is a block diagram of an exemplary embodiment of...

...across the media.

Fig. 8 is a schematic block diagram of an embodiment of the **modular backup** system according to the invention.

Fig. 9 is a schematic block representation of an embodiment... configuration of the software agents.

5

Fig. 12 is a functional block diagram of the **modular backup** system of Fig. 8 where a computing **device** contains a management component and a **media** component for the archival of **information** from the attached computing **devices**.

6

DETAILED DESCRIPTION OF THE INVENTION

Fig. 1 is a schematic block diagram of a...218 include the functionality associated with a management module, or the overall management of the **modular backup** system.

The application sub-agent 210 stores configuration parameters and current states for each application...12

Fig. 3 is a logical block diagram of the various possible interconnections between the **modular** portions of the **backup** system of Fig. 1. A manager module 300 communicates with the various other modules in...

...350, 360, and 370 ible for the backup and archival processes for a particular computing **device**. The are responsi
manager module 300 is communicatively coupled with each of the respective client...

...order to direct a cohesive systemwide backup policy involving the backup of each individual computing **device** that the particular client modules are responsible for.

Media modules 310 and 320 are also...

...the media modules 310 and 320 are responsible for operating and maintaining, respectively. Thus, a **modular**, interconnected backup system is shown.

Fig. 4 is a block diagram of an exemplary embodiment of the...the file
740 Fig. 8 is a schematic block diagram of an embodiment of the **modular backup** system according to the invention. Typically, a **modular**

backup system 800 comprises several software components, including a management component 810 communicatively coupled to least...

...or contain their functionality

1 5

as included modules. As such, the components of the **modular storage** and **retrieval** system 800 of a management component 810, the client component 820, and the **media** component 830 are typically **software** programs running on the respective computing **devices** .

A management component 810 is the software agent that can control the actions...through the media component 830.

Fig. 12 is a functional block diagram of the **modular backup** system of Fig. 8 where a computing **device** contains a management component and a **media** component for the archival of information from the attached computing **devices** . A computing **device** 1210 contains a

26

management component 1211 and a **media** component of 1212. The computing **device** 1210

1212 manages and directs

communicates with a library **media** 1215. The **media** component archival functions on the library **media** 1215.

A computing device 1220 containing a client component 1221 communicates with the computing device...

Claim

... the management software component controls backup functions for the plurality of network devices.

15 The **backup** and **retrieval** system of claim 11 wherein the media **software** component creates an **index** of information on the location of archived information on the storage device, and communicates at least part of the **index** of information to the management **software** component.

30

. A **backup** and **retrieval** system for a network, the network comprising a plurality of computing devices, the plurality of...

...wherein the management component software controls backups of the plurality of computing devices.

18 The **backup** and **retrieval** system of claim 16 wherein the media component **software** creates an **index** of information on the location of archived information on the at least one **backup** device, and communicates at least part of the **index** of information to the management component **software** .

31

. The **backup** and **retrieval** system of claim 16 wherein the management component

I

software and the media component software...

... requested by SisCSFilesToBackUpForLink, described
below. If countOfCommonStoreFilesToBackUp is zero, then
commonStoreFilesToBackUp may be a NULL **pointer** and should
be ignored by the **backup application** 118.

The return value is TRUE if the call succeeded, and
FALSE otherwise. If FALSE...

...its tag, IO-REPARSE-TAG-SIS.

For each SIS link to be backed up, the **backup application**
118 should call (only once per link file)
SisCSFilesToBackUpForLink.

The SisCSFilesToBackUpForLink function takes as
input a **pointer** to the contents of the SIS reparse point
for a link file that the **backup application** 118 is
planning to store on the backup storage medium 122. This
function also takes the length of the reparse data as a
parameter, as well as an optional context **pointer** that is
provided by the **backup application** and uninterpreted by
the SIS DLL 116.

In accordance with one aspect of the present...of FIG. 13B first zeros
the count of
files to return and sets the array **pointer** to NULL,
whereby the **backup application** 118 will not receive a
common store filename unless needed. To this end, step
1322...

...returned status, and adds its
filename string to the array for returning to the backup
application. At step 1326 the
countOfCommonStoreFilesToBackUp and
commonStoreFilesToBackUp are appropriately adjusted,
after which step 1328 returns the array (i.e., its
pointer) and count to the **backup application** 118. Note
that multiple common store files corresponding to a link
file may be handled...

BACKGROUND

1. Technical Field.

The present...

...computer networks. In particular, the present invention is directed
towards the implementation- of a distributed, **modular backup** system
with a storage area network (SAN) system, and the use of the **modular**
ID
backup system under the SAN file system.

. Related Art.

Conventional backup devices usually employ a monolithic...

...computing devices may be interconnected. In still other embodiments, the
storage system may include a **modular backup** system that works in
conjunction with a **storage** area network (SAN) system. Of

.D

course, the information in the storage system may be **data** or files
and the computing **device**

2)

may include an attached **data storage device**, to which it can store
data and files locally. The computing **devices** of the **storage** system
may be connected to the SAN system via a direct fiber channel connection,
a...

...follow.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a schematic block diagram of a **modular backup** and
retrieval system built in accordance with principles according to the
present invention.

ID

Flu. 2 is a schematic block diagram of a **modular backup** system
working in conjunction with a **storage** area network (SAN) system
according to principles of the present

0
invention.

Fig. 3 is...

...system maintained by the SAN system implementing a path extension to data archived by the **modular backup** system, all of Fig. 2.

DETAILED DESCRIPTION OF THE DRAWINGS

Fig. 1 is a schematic block diagram of a **modular backup** system. A **modular backup** system 100 comprises three components, a management component 110, one or more client components 120, and one or more **media** components 130.

Typically, the three components comprising the management component 110, the client component 120...D computing devices may be interconnected.

Fig. 2 is a schematic block diagram of a **modular backup** system working in conjunction with a **storage** area network (SAN) system 250. A computing **device** 200 contains and operates a management component 202, which is responsible for the coordination of backup, **storage**, retrieval, and restoration of files and **data** on a computer network system 290. The management component 202 coordinates the aspects of these functions with a client component 212, running on another computing **device** 210, and a client component 222 running on yet another computing **device** 220. The computing **device** 220 also has an attached **data storage device** 214, to which it can store **data** and files locally.

The computing devices 210, 220, and 230 are connected to the SAN...file processor of a SAN system implementing a path extension to data archived by the **modular backup** system, all of Fig. 2. The normal network file system has a root directory "/", with various partitions relating to different functions and or different **data** sets as determined by the functions and configurations of the computing **devices** 210, 220, and 230, all of Fig. 2. In this embodiment, the **archived** portion of the network file system resides in the Subdirectory "Backups/".

As each archive backup...

Claim

... the computing devices are interconnected.

6 The storage system of claim 1 further comprising a **modular backup** system that . The **storage** system of claim 1 wherein the **information** in the **storage** system comprises **data** . S. The **storage** system of claim 1 wherein the information in the **storage** system comprises files.

9 The storage system of claim 1 wherein the computing device further...

Abstract: We propose a new mutually coupled plural neural networks (NN) **modules** and its **application** to associative memories from the view point of noncooperative game theory. First, we propose a new dynamical searching model named parallel steepest descent method with braking operators (PSDMB) which searches the Nash equilibrium (NE) points under $[0, 1]$ -interval or nonnegative constraints. Second, we propose a new mutually coupled plural NN modules named game neural networks (GNN) to realize the proposed PSDMB with quadratic objective functions. In addition, we indicate relations between the PSDMB, the GNN and the Lotka-Volterra equation. Last, for an application of the proposed GNN, we propose two kinds of multimodular associative memories which can associate the combined patterns composed of plural partial patterns: (1) the combined patterns are stored as the NE points and robust for noisy inputs; (2) the circulative sequence of the combined patterns are stored as saddles of a heteroclinic cycle. (6 Refs)

Abstract: This paper presents a **modular software** system, which classifies a large variety of office documents according to layout form and textual content. It consists of the following components: layout analysis, pre-classification, OCR interface, fuzzy string matching, text categorization, and lexical, syntactical and semantic analysis. The system has been applied to the following tasks: presorting of forms, reports and letters, **index** extraction for archiving and **retrieval**, page type classification and text column analysis of real estate register documents, in-house mail sorting and electronic distribution to departments. The architecture, modules, and practical results are described. (11 Refs)

Abstract: Reports on an implementation of P. Kanerva's (1988, 1992) sparse distributed memory (SDM) for the Connection Machine. In order to accomplish a **modular** and adaptive **software** library, we applied a plain object-oriented programming style to the Common Lisp extension *lisp. Some variations of the original model-the selected coordinate design, the hyperplane design and a new general design, as well as the folded SDM due to Kanerva-are realized. It has been necessary to elaborate a uniform presentation of the theoretical foundations the different designs are based on. We demonstrate the simulator's functionality with some simple applications. Runtime comparisons are given. We encourage the use of our

simulation tool when outlining research topics of special interest to SDM.

Abstract: SEED is a collection of **software modules** intended to support the early phases of building design. The system incorporates the results from two multi-generational research efforts on grammar-based design generation and offers designers a broad range of form generation tools, from interactive construction that is controlled by the designer to the automated generation of design alternatives and case-based design. The system will eventually combine these capabilities with a broad range of analysis, evaluation, and visualization tools. The SEED modules are based on a shared logic and are accessible through a shared interface. This logic results from a uniform problem-solving view underlying the tasks supported

by modules. The key is a uniform problem specification based on functional units which allow a module to participate actively in form generation and support a uniform case **indexing** and **retrieval** mechanism across modules and across problem decompositions within a module. (18 Refs)

Abstract: VLSI architectures for neural networks are presented. Neural networks have wide-ranging applications in classification, control, and optimization. With the need for real-time performance, VLSI neural networks have gained significant attention. Digital, analog, and mixed-mode designs are used for this **application**. **Modular** and reconfigurable designs are necessary so that various neural network models can be easily configured.

Language: English Document Type: Journal Paper (JP)

Treatment: Theoretical (T)

Abstract: Proposes an extension to the recursive auto-associative memory (RAAM) by Pollack. This extension, the labelling RRAM (LRARM), can encode labelled graphs with cycles by representing pointers explicitly. Some technical problems encountered in the RRAM; such as the termination problem in the learning and decoding processes, are solved more naturally in the LRAAM framework. The representations developed for the pointers seem to be robust to recurrent decoding along a cycle. Theoretical and experimental results show that the performances of the proposed learning scheme depend on the way the graphs are represented in the training set. Critical features for the representation are cycles and confluent pointers. Data encoded in a LRAAM can be accessed by a pointer as well as by content. Direct access by content can be achieved by transforming the encoder network of the LRARM into a particular bidirectional associative memory (BAM). Statistics performed on different instances of LRAAM show a strict connection between the associated BAM and a standard BAM. Different access procedures can be defined depending on the access key. The access procedures are not wholly reliable; however, they seem to have a good success rate. The generalization test for the RAAM is no longer complete for the LRAAM. Some suggestions on how to solve this problem are given. Some results on **modular** LRAAM, stability and **application** to neural dynamics control are summarized. (31 Refs)

Treatment: Theoretical (T)

Abstract: The labeling RAAM (LRAAM) is a neural network able to encode data structures in fixed size patterns, thus allowing the **application** of neural networks to structured domains. Moreover, the structures stored into an LRAAM can be accessed both by **pointer** and by content. In this paper we briefly discuss basic and generalized associative access procedures for the LRAAM. Basic procedures are obtained by transforming the LRAAM network into a BAM. Different constrained versions of the BAM are used depending on the key(s) used to **retrieve** information. Generalized procedures are implemented by generalized Hopfield networks (GHN) which are built both by composing the subset of weights compounding the LRAAM and according to the query used to **retrieve** information. Some examples for generalized procedures are given. (19 Refs)

Abstract: Massively parallel computers (MPCs) are playing an important role in providing powerful computing environments for a wide variety of computationally intensive applications requiring up to tera-operations per second (TOPS) performance levels. Associative processing involves a particularly flexible and naturally parallel form of symbolic representation and manipulation of structured data processing (via sets, arrays, tables, trees and graphs) with potential benefits in simplicity of expression, storage capacity, and speed of execution over a wide range of non-numerical and numerical information processing applications. Emerging from long-term research at Brunel University (UK) and being developed by Aspek Microsystems, ASP (Associative String Processor) **modules** (and support **software**) comprise highly versatile and fault-tolerant building-blocks for the simple construction of dynamically reconfigurable low-MIMD/high-SIMD second-generation MPC systems. The ASP offers step-function improvements in the size, weight, power consumption,

reliability, and implementation costs of numeric and symbolic information processing systems. ASP modules offer the prospect of breaking through the cost-effectiveness barrier currently impeding the wider commercial exploitation of massively parallel computing systems. It can be predicted that traditional supercomputers will be superseded by massively parallel computers. Cost-effective embedded MPCs could stimulate a much larger supercomputer market than that estimated to reach \$1 billion by 1996. (0 Refs)

Language: English Document Type: Journal Paper (JP)

Treatment: Practical (P)

Abstract: The design of a fast, versatile associative module (AM) increasing the conversion gain of multichannel analyzers (MA) in multiparameter measurements is reported. The design is especially suitable for pulse height spectrum measurements from high counting rate sources as would be found in reactor sample on-line monitoring systems, being able to acquire spectrum data at input rates in excess of 10^5 Hz. Specific characteristics of the instrumentation are as follows: 1) the system's basic structure is implemented by one multichannel analyzer and one associative **module**, and allows a **programmable** conversion gain. The maximum achievable conversion gain is 2×10^6 . If the MA dead time is shorter than the AM dead time, the dead time of the system is equal to 340 ns. 2) The basic structure can be expanded vertically and horizontally; the expanded structures keep the original speed of the basic one. The MA conversion varies according to the AM selected expansion, ranging from 2×10^4 to 2×10^6 ; 3) to solve the problem of fast real-time spectrum acquisition speed, fast electronics is used. Electronics is autonomous in the spectrum acquisition, updating and graphical phases, while it is under computer control in both phases of the system's initialization and for transfer of the updated spectrum data from the MA buffer memory unit to the host; and 4) the system is constructed from commercially available components. Their high integration and speed have led to a powerful, compact, flexible instrumentation system while minimizing cost at the same time. (17 Refs)

Abstract: Since the restructuring of the curriculum of the Dutch Library and Information Science Schools, the curriculum emphasises the information needs of the user and the intermediate role of the information professional. In the fourth and final year students must choose one of the three available 'majors' and a terminal project corresponding with the chosen major. Software evaluation is one of the modules comprising the major in **indexing** systems and information technology. The main objectives of the **software** evaluation **module** are: the student gains a basic knowledge of and insight into the different phases of the automation development process in general and of the information environment in particular; the student can individually evaluate software on the basis of specific criteria; the student is capable of 'transferring' the results of these evaluations both orally and in written form during plenary sessions; the student is capable of comparing information storage and **retrieval** systems (ISRS) and (integrated) library software packages; and the student is capable of drawing individual conclusions and making recommendations, resulting in individual advice to the manager. Treatment: Practical (P); Product Review (R)

Abstract: The Gmelin Information System presents scientific information in the fields of inorganic, organometallic and physical chemistry on two different media, the Gmelin Handbook and the Gmelin Factual Database. Both components, the handbook and the factual database, will be integrated into the Gmelin Information System. Therefore, the primary information for

handbook production (information about compounds, facts, and bibliographic data) will be delivered from the Gmelin Database. The main qualities, of both the handbook, which are described and of the database (availability of online factual information) should be able to be retained. As a software interface between the handbook and the database, the authors have developed for Gmelin Electronic Card **Index** . It is the card file for handbook production and employs advanced methods of electronic data processing. The development was based on the hypertext program CAMS4 (Juniper Systems Partnership). The new developments for the Gmelin Electronic Card **Index** include a flexible generator of database templates and functions for direct access to ADABAS database files under VAX/VMS. A **program module** for creating a separated working set was implemented for use in the handbook department. This working set allows handling of database contents without direct access to ADABAS. Title: The implementation of BASIS at the Imperial Cancer Research Fund

Author(s): Davies, M.

Author Affiliation: Libr. & Inf. Services, Imperial Cancer Res. Fund, London, UK

Journal: Program vol.25, no.3 p.187-206

Publication Date: July 1991 Country of Publication: UK

CODEN: PRGMBD ISSN: 0033-0337

Language: English Document Type: Journal Paper (JP)

Treatment: Practical (P)

Abstract: A summary is given of the factors influencing the selection and implementation of BASIS (release K) and its library application packages (TechLib/STACS/BILL) in the creation of seven end user databases at the Imperial Cancer Research Fund (ICRF). The Science Citation **Index** source tapes are used to provide a current-awareness service and an online search service of the latest six months of data. A full-text database of scientific reports, and details of staff publications and staff laboratories is created. The BILL (British Interlibrary Loans) module of

BASIS is used for the large number (12000+p.a.) of interlibrary loans and photocopy requests at ICRF. The emphasis is on local requirements and customisation of the **program modules** for end users rather than a detailed description of their standard features. (5 Refs)

Abstract: A new memory model of optical neural networks called the reflexive associative memory is implemented in real-time using programmable liquid crystal television (LCTV). In this model the vectors are stored in a memory matrix in the form of vector pairs. Not only a full vector prestored in neural networks can be recalled from partial information of the vector, but the other vector of the prestored vector pair can also be recalled. (6 Refs)

Abstract: The authors report on a tungsten-oxide-based, nonvolatile, electrically reprogrammable, variable resistance device as an analog synaptic memory connection for electronic neural networks. A voltage controlled, reversible injection of H^{+} ions in electrochromic thin films of WO_3 is utilized to modulate its resistance. A hygroscopic thin film of Cr_2O_3 is the source of H^{+} ions. The resistance of the device can be tailored and stabilized over a wide dynamic range (approximately four orders of magnitude), and the programming speed is modulated by the control voltage. The suitability of such a device in terms of its response speed, reversibility, stability, and cyclability for its use in electronic neural networks is discussed. (10 Refs)

Abstract: The authors describe their work on the development of opto-electronic devices with intrinsic properties conducive to simulating neurons and synaptic interconnections. These devices permit a novel architecture for the optical implementation of Hopfield's neural network model for associative memory applications with the feedback in the optical domain. Eliminating the need for electronic feedback circuits would permit larger networks to be implemented. (14 Refs)

Title: **MVSE 51-a small development system for microcomputers of the 8051 series**

Author(s): Smolka, J.; Bajbar, J.; Lukovic, T.; Pernecky, M.

Journal: Sdelovaci Technika vol.37, no.4 p.125-7

Publication Date: April 1989 Country of Publication: Czechoslovakia

CODEN: SDTEAM ISSN: 0036-9942

Language: Czech Document Type: Journal Paper (JP)

Treatment: Practical (P)

Abstract: Describes the hardware and software of the MVSE 51 system which is an effective tool for the development and debugging of microcomputer systems. The system is designed for maximum utilisation of the **addressing storage** space. External memory can be used either for programs or data. User communication is facilitated by means of an alphanumerical terminal with a keyboard (Videoton 52 100, SM 1601, SM 7202). The software of the MVSE 51 system consists of three independent parts-the basic monitor; extended software based on a minimonitor; and interactive **software** for controlling **programming modules** . Treatment: Practical (P)

Abstract: The management of documents, that have a data content that is expressed in graphic symbolism, can be classified into three basic tasks: storage and **retrieval** of the documents, maintenance (revision) of the documents, dissemination (distribution) of the documents. In an OD/DMS, the dissemination of the image data requires special considerations in the choice of the communication channels. The systems that are offered on the market can be divided into two basic categories: data private branch exchange (data PBX) systems and local area network (LAN) systems. The author discusses the differences between these systems and goes on to look at the OD/DMS environment, i.e. **indexing**, document address assignment, task-specific **software modules**, **index** and control **program** storage, workstations and printers. OD/DMS architectures are also considered. (0 Refs)

Treatment: Practical (P)

Abstract: The authors examine experimentally and theoretically two devices based on III-V technology, which are critical in the implementation of the Hopfield model as well as other neural type networks for associative memories. The devices are based on Stark effect of excitonic transitions. P-i (multiquantum wells)-n structures using GaAs/AlGaAs provide a controller-modulator device which has the integrating-thresholding properties required of neurons. The p-i-n structures also provide **programmable modulators** which can serve as a synaptic mask. Using Monte Carlo techniques, the authors examine an all-optical architecture to implement the Hopfield network. No external feedback-thresholding circuitry is required in this implementation due to special design of the controller-modulator device. Speed and stability issues of this architecture are also addressed. The computer simulation results provide insight into how the controller-modulator device should be improved for better network implementation. The basic technology now exists for such an implementation. (21 Refs)

Treatment: Practical (P)

Abstract: Self-organization and learning is a distinctive feature of neural nets and processors that sets them apart from conventional approaches to signal processing. It leads to self-programmability which alleviates the problem of programming complexity in artificial neural nets. In this paper architectures for partitioning an optoelectronic analog of a neural net into distinct layers with prescribed interconnectivity pattern to enable stochastic learning by simulated annealing in the context of a Boltzmann machine are presented. Stochastic learning is of interest because of its relevance to the role of noise in biological neural nets. Practical considerations and methodologies for appreciably accelerating stochastic learning in such a multilayered net are described. These include the use of parallel optical computing of the global energy of the net, the use of fast

nonvolatile **programmable** spatial light **modulators** to realize fast plasticity, optical generation of random number arrays, and an adaptive noisy thresholding scheme that also makes stochastic learning more biologically plausible. The findings reported predict optoelectronic chips that can be used in the realization of optical learning machines. (49 Refs)

Abstract: A fuzzy associative memory (FAM) is a device in which data in memory are located and manipulated on the basis of the values of the data themselves. This processing is based on ranges of values (fuzzy), not specific points. This makes the device more applicable to real-world problems. A FAM currently under development is described. It is intended as a high-speed association coprocessor for signal and data processors. In addition, the FAM's potential for supplying practical solutions to previously difficult multivariate detection and estimation problems is investigated and some analytic tools are presented. Abstract: The Utah Text **Retrieval** Project is capable of handling databases ranging in size from electronic file cabinets to large information utilities; it offers good response time, a straightforward but powerful user interface, and reasonable cost. **Software modules** can be replaced by special-purpose backend processors to improve the system performance. A message-based approach allows a number of significant advantages over existing **retrieval** systems. Processing can be distributed among a number of conventional or special-purpose processors. The **retrieval** system can function as a backend system driven by a number of workstations, since the design supports multiple host processors. Modules

performing key system tasks, such as **index** manipulation or searching, can be altered to perform more efficiently in a particular application or be replaced by backend hardware systems. A prototype of the system is currently operational on a network of Apollo workstations. (3 Refs)

Abstract: The microcomputer-based **modular software** package MINDOK was developed to support the application of documentation systems to routinely typed documents like reports, letters, etc., to make available the contained information for **retrieval** and research. It provides functions for the generation of input and output forms, word processing and error checking in data and free-text. Documents have to be typed only once. They can be reformatted and used for different purposes. Automatic **indexing** as well as storage and **retrieval** operations are supported too. **Retrieval** is possible in locally stored inverted files, in the MINDOK data base on minicomputers and mainframe documentation systems. By these features MINDOK supports comprehensively the complete document generation, analysis and **retrieval** process. (4 Refs)

Conference Date: 3-4 April 1978 Conference Location: Leeds, UK

Language: English Document Type: Conference Paper (PA); Journal Paper (JP)

Treatment: Practical (P)

Abstract: This paper is concerned with the design and implementation of an information system, called BINSYS, for use by the non-expert and which is applicable within a wide range of subject areas. Like most other information systems, BINSYS offers its user facilities for data capture or accession of items, classification through the assignment of descriptor codes, **retrieval** via conventional permuted **indexes** and online searching using keywords in conjunction with a semantic network, updating of the stored information and **indexes** as a result of the acquisition of new knowledge, reclassification or the elimination, of material that is no longer of value, the capability to handle multimedia materials, simplicity of operation since there are relatively few **program modules** and transportability of data and software. BINSYS contains a data dictionary that enables logical descriptor codes to be mapped onto physical storage. It is through the data dictionary that mobility and ease of transportation of data is achieved. It also offers some degree of privacy of information through the use of enciphering techniques applied to its entries. The basic structure of the system is hierarchical although both network and relational components are present as discrete components and some network interactions may be formulated within the overall system. Abstract: SCORPIO (Subject Content Oriented **Retriever** for Processing Information On-line) is a terminal independent, interactive information system, within the DIALOG/RECON family of **retrieval** systems, under development at the Library of Congress. From over 40 terminals located in the Library and the Congress, staff members use SCORPIO to **retrieve** both legislative and bibliographic information from Library data bases with an average response time of less than five seconds. The implementation philosophy allows **program modules** that provide new capabilities to be implemented rapidly while minimizing development costs and maximizing customer satisfaction.

CODEN: IFSRAS ISSN: 0020-0271

Language: English Document Type: Journal Paper (JP)

Treatment: Practical (P)

Abstract: The computer Search Center (CSC) at IIT Research Institute (IITRI) provides information from computer-readable data bases to users in industry, government and universities. The centre was designed to meet user needs by providing a variety of services from multiple data bases with minimal restrictions and a high degree of flexibility. A new modular machine-independent PL/1 software system was developed for handling virtually any bibliographic-type data base. CSC programs have run at nine different computer facilities with different hardware, computer models, versions of OS, peripherals, and releases of the PL/1 compiler. All data bases are converted by preprocessors to a standard IITRI format which employs a directory and character string type of file structure. User

oriented profile features include: full free form Boolean logic with any degree of nesting; search terms may be any data element on a data base; search terms may be single words, multi-word terms, phrases, or term fragments; full truncation capabilities; optional sort by author, citation number, or weight; and optional printing of output on 5*8 cards, multilith masters, paper, or tape. User aids were developed for each data base to assist in profile development and monitoring. They include: search manuals, truncation guides, term frequency list and KLIC **indexes** . (5 Refs)

Title: An information organizer for coordinating modular programs

Author(s): Hatfield, F.J.

University: Univ. Illinois, Urbana, IL, USA

Dissertation Date: 1970

Country of Publication: USA 170 pp.

Availability: Univ. Microfilms, Ann Arbor, MI, USA Order No. 71-14785

Language: English Document Type: Dissertation (DS)

Treatment: Practical (P)

Abstract: What is needed is a standard, self-documenting data structure suitable for input and output by a wide range of engineering programs. The information organizer provides such a structure, together with variable, arrays and subroutines for manipulating the structure. The structure is conceptually a set of hierarchically nested tables. A row-column intersection of a table may contain either a word of data or a nested table. Associated with each column of a table, and therefore with the data or tables nested into that column, is an alphanumeric label. The column labels, which reside in secondary storage with the data, serve both as a data directory and as mnemonic documentation of the structure. The information organizer provides facilities for creating and deleting rows and columns, for sorting and **indexing** the rows of a table, for addressing columns by label, and for addressing rows by either value or position. The frequency of relatively slow **retrievals** of secondary storage records is minimized by retaining in primary storage previously **retrieved** records in anticipation of future needs according to a strategy based on the number and currency of past accesses of each record.

FORMALIZATION OF STORAGE CONSIDERATIONS IN SOFTWARE DESIGN (MEMORY, MODULAR REASONING)

Author: ANKIREDDIPALLY, LAKSHMINARASIMHA REDDY

Degree: PH.D.

Year: 1999

Corporate Source/Institution: WEST VIRGINIA UNIVERSITY (0256)

PAGE 2776. 110 PAGES

Descriptors: COMPUTER SCIENCE

Descriptor Codes: 0984

One of the technical impediments for the widespread adoption of the formal methods is an inability to **address storage**-related concerns such as "out of memory" errors. The focus of this dissertation is on formal specification and modular reasoning of storage-related aspects of practical components and systems. In particular, this thesis tries to address the following fundamental storage-related questions for practical component-based software development (1) Is it possible to reason statically and in a modular fashion that the system would not run "out of memory"? (2) Is it possible for the reasoning system to be modular, yet sufficiently precise with respect to storage constraints? (3) Is it possible to have a formally specified storage management mechanism that is predictable and efficient, yet allows effective storage utilization?

The main contribution of this research work is a formal and modular framework for storage specification and reasoning. A memory management mechanism that is predictable and efficient is also a part of this dissertation.

THE DESIGN AND IMPLEMENTATION OF A CT/MR PICTURE ARCHIVING AND COMMUNICATION SYSTEM APPLIED TO NEURORADIOLOGY

Author: LOU, SHYH-LIANG

Degree: PH.D.

Year: 1991

Corporate Source/Institution: UNIVERSITY OF CALIFORNIA, LOS ANGELES (0031)

Chair: H. K. HUANG

Source: VOLUME 52/03-B OF DISSERTATION ABSTRACTS INTERNATIONAL.
PAGE 1383. 185 PAGES

Descriptors: HEALTH SCIENCES, RADIOLOGY; BIOPHYSICS, MEDICAL

Descriptor Codes: 0574; 0760

An increasing number of digital images are being generated by radiology departments. The digital imaging modalities are distributed over geographically separate hospital buildings and, therefore, the management of multi-modality images for a patient is not easy. This dissertation presents the design and implementation of a picture archiving and communication system (PACS) that can provide fast access to CT and MR images for neuroradiology applications. The course of this dissertation proceeded in four steps: (1) research of the film management operation in the neuroradiology division, (2) integration of hardware components, (3)

integration of **software modules** , (4) clinical evaluation.

The fundamental tasks of the PACS system are modularized into four subsystems (image acquisition, management, communication and display). An Ethernet digital communication network serves the task of data transportation between computer systems within the PACS. Image data is automatically acquired from three CT and three MR scanners by four SUN minicomputers. The acquired images are managed by a SUN server computer and are stored on magnetic disks for fast access and on an automated optical disk library for long term archival. A SUN-PIXAR based workstation with four 1280 x 1024 line monitors is used for image display.

A communication software based upon TCP/IP is implemented to transfer image data over Ethernet. Patient demographic information and associated images are processed by database management processes. The database management include database **index** file maintenance, image archival, **retrieval** , distribution, and deletion. Images are fully replicated in the display workstation. In the workstation, a mouse-and-menu interface allows users to display and manipulate images.

Since February 1990, over 10,000 digital images (37 Gbytes) have been archived, and over 1,600 viewing sessions have been conducted using the display workstation. On average, 41.8 and 8.6 minutes are required to deliver one CT and one MR image study, respectively, from the image scanner to the display workstation. To **retrieve** an archived image study for viewing, 2.4 and 1.04 minutes are needed for one CT study and for one MR study, respectively. Survey responses from ten radiologists evaluating eight workstation operations express overall system acceptance.

Document Type: Software Review

Grade (of Product Reviewed): B

Hardware/Software Compatibility: IBM PC Compatible; Microsoft Windows

Geographic Location: United States

Presents a favorable review of LaserFiche (\$495), a document management program from CompuLink Management (310). The **program** provides an OCR **module** and provides a database in which to store documents. It is Windows-based and available in several versions, including a standalone version and a client-server version for NetWare. It can scan multipage documents and store images in its database. It supports the use of keywords for categories to aid in document **retrieval** and its search engine supports ``fuzzy'' searches. The program allows users to **index** text so they can search the contents of a document. Upcoming versions of the program are expected to support gray-scale and color images and provide import and export capability for Microsoft Word for Windows and WordPerfect for Windows document files. Includes one screen display. (djd)

Abstract (Basic): WO 200155857 A2

NOVELTY - Several storage media (108,110-112) are communicatively connected to a processor that supports operation of any one software application (102). The software application has a **retrieval** module which **retrieves** data from the storage media, based on the data location specified by storage and **backup** map (106).

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for data **retrieval** method.

USE - For use in computer system.

ADVANTAGE - Since the storage and **backup** specifies the required location for data **retrieval**, the user is not required to know the latest location of data in the storage media, thus **retrieval** of data from many types of storage media is enabled without assistance beyond the **retrieval** system. Allows end users to view and access in the

logical format that they are used to with their applications or systems.

DESCRIPTION OF DRAWING(S) - The figure shows block diagram of data **retrieval** system.

Software application (102)

Abstract (Basic): WO 200106368 A1

NOVELTY - The manager module in computer (110) is in communication with media modules (126,136) of computers (120,130). Media modules are coupled to library devices (122,132). The media module controls physical **backup** of data onto library devices and manager module controls media module and also manages overall **backup** and **retrieval** functions.

USE - For controlling data **backup** in computers or network connected computer.

ADVANTAGE - The independent software agents, manager module and software module, focus specifically on archival process and are cohesively operated in network environment across several machines.

DESCRIPTION OF DRAWING(S) - The figure shows the block diagram of modular network **backup** system.

ABSTRACT

PROBLEM TO BE SOLVED: To provide a game machine improved to reproduce an original game as much as possible with power voltage variations or other electric troubles in restarting an interrupted game operation.

SOLUTION: A control **program** of this pachinko machine incorporates a first process started in responding to turning-on of a power and ordinarily finished by an infinite loop process, a second process repeatedly executed for every prescribed times T, and a third process forcedly started when the power voltage is lowered from a normal level. In the third process, a **backup** flag showing the completion of **data** retreat to a prescribed **storage** area is set and a value of a stack **pointer** is stored in a prescribed **storage** area. In the first process, the **backup** flag is reset and the **storage** area is cleared.

ABSTRACT

PROBLEM TO BE SOLVED: To realize the retry processor making it possible to secure the continuity of the processing of a computer system by a bus trace and a **backup** memory also even at the production of an error.

SOLUTION: The **data** of a **data** bus 6, an address bus 7 and a control line 8 is normally held in a trace memory 3. When written in a main **storage device** 2, the **data** before the writing is held in the trace memory 3. A

CPU 1 writes the values of the register, the **program** counter and the stack **pointer** within the CPU 1 as the checkpoints for every fixed interval in the **storage device** 2. When an error is produced, an error cause is analyzed, the checkpoint to perform a retry processing is determined, the **data** of the trace memory 3 is written in the **storage device** 2, the contents of the main **storage device** 2 and the register, the **program** counter and the stack **pointer** of the CPU 1 is returned to the contents of the checkpoint to perform the retry processing, the retry processing is started and a **program** is returned to a normal **program** .

ABSTRACT

PURPOSE: To provide the **programmable** controller which has an error retrying processing function that enables the continuation of the execution of a **program** without stopping the **program** even if a transient error having wide time width occurs.

CONSTITUTION: This **programmable** controller which operates in optional scanning cycles is equipped with a retrying processing means 42 which tries the reexecution of an instruction where an error occurs, an error **address storage** means 52 which stores the address where the error occurs unless the operation of the **program** recovers through the retrying processing means 42, a scanning cycle ending means 44 which ends the corresponding scanning cycle unless the operation of the **program** recovers through the retrying processing means 42, and execution stopping means 43 and 45 which stops the execution of the whole **program** when the address of the stored error is the same address throughout two successive scanning cycles.

ABSTRACT

PURPOSE: To facilitate the recovery of a failure when it is detected by rewriting a microprogram so as to make the next execution instruction control storage **program** serve as a substitute address.

CONSTITUTION: When a microprogram is read out of a failure occurrence control storage entry ECSE 112 pointed by a current control **storage address** register CCSAR 104, a failure detector 101 checks the failure and reports this checking result to a failure processor 120. The processor 120 prevents the execution of the microprogram having the failure. Then the processor 120 points a substitute control storage entry SCSE 113 and transfers and stores the copy of the microprogram stored in the ECSE 112 shown in the CCSAR 104 to a storage 103. Furthermore the processor 120 points a control storage entry BCSE 111 shown in a precedent control **storage address** register BCSAR 121 and rewrites the next execution control **storage entry address** field into an address which points the SCSE 113.

ABSTRACT

PURPOSE: To provide a **device** by which the change of the **program** of a subprocessor can be easily performed and error recovery can be performed as an **information** processor capable of saving power consumption and comprised of multiprocessors.

CONSTITUTION: This processor is the **information** processor of multiprocessor system comprised of a main processor part 1, a subprocessor part 2, and a power source part 3, and a power source is always supplied to the subprocessor part 2 from a **backup** power source 32. An error notifying means 24 is provided at the subprocessor part 2, and when an error is

detected in the subprocessor part 2, the occurrence of the error in the subprocessor part 2 is displayed, and a main power source 31 is supplied to the subprocessor part 2 via a power source control interface 25 and a main power source control circuit 33, and the main processor part 1 checks a content displayed by the error notifying means 24 after performing start-up processing, and reads out the control **program** of the subprocessor from external **storage** 4 when detecting the occurrence of the error in the subprocessor part 2, and loads it on the memory 22 of the subprocessor 2 via an inter-processor communication means 26.

ABSTRACT

PURPOSE: To reduce the capacity of an external **storage device** by providing the correspondence allocation table of a **program** area and compressing the **backup** file of a **program** on a main **storage device** so as to provided it on the external **storage device** .

CONSTITUTION: The main **storage device** 1 is provided with the correspondence allocation table (TBL) 11 of the **program** area 12 and the **program** area on the **backup** file 21 in a hard disk 2. The leading address and the tailing address of the areas in using **programs** A and B in the **program** area 12, and the leading addresses of **program** areas A' and B' in the **backup** file 21 are correspondingly allocated to TBL 11 and are controlled. When the tailing address of the area of the using **program** A and the leading address of the area in the using **program** B are allowed to correspond to the leading address of the **program** area B' in the **backup** file 21, the area of an unused **program** (a) is not allocated to the **backup** file 21. Thus, the capacity of the hard disk can be reduced.

ABSTRACT

PURPOSE: To obtain a processing speed corresponding to the extent of emergency by performing a check point process and a roll-back process by using a save area in a main storage as to a **program** which is high in the extent of emergency.

CONSTITUTION: When the extent of emergency of the **program** 100 is larger than a specific threshold value, an in-main-storage save area assigning means 3 operates assigns the save area of size satisfying size set in a data area table 12 in the main storage and uses the area as the in-main-storage save area 101. Further, the in-main-storage save area assigning means 3 generates a save area control table 13 in the main storage 10 to set a main storage presence flag on and also store the main **storage address** of the assigned in-main-storage save area 101 in a save area control table 13. Then the check-point process and roll-back process are performed. Consequently, the **program** which is high in the extent of emergency is processed in a short time.

JOURNAL: Section: P, Section No. 555, Vol. 11, No. 79, Pg. 58, March
11, 1987 (19870311)

ABSTRACT

PURPOSE: To prevent the titled process from becoming a state that a common bus remains occupied at the time of an error, by halting the occupancy of the bus, in case when a control storage parity error has been generated before starting Write, and starting a retry based on the contents of a specified register, after a control storage has been reloaded.

CONSTITUTION: An output of a control **storage address** register, an output 51 of a reserve flag, and an output 67 of a save register can be loaded on a data bus 75, therefore, a **program** of an auxiliary processor can know their contents. When a selection of a control signal is also executed by a decoder 77, and write signal 76 is turned on, a start signal

48, or a control storage write signal 50, or a control **storage address** register change signal 65 can be turned on, and the **program** of the auxiliary processor can control these signals. A signal 88, a signal 89, a signal 90, a signal 91, a signal 93, and a signal 61 are set by a bus occupancy request signal, a bus occupancy permitting signal, a read command signal, a write command signal, a response signal, and when a control storage parity error has been generated, respectively. In case when the control storage parity error has been generated in the course of Read-Modify-Write, the bus reserve is released.

ABSTRACT

PURPOSE: To attain economy by using a magnetic tape **device** as an external **storage device** to unify the external **storage device** .

CONSTITUTION: Sub-channels 20a, 20b are connected to duplicated central controllers 10a, 10b and cartridge magnetic tape **devices** 60a, 60b and typewriters 80a, 80b are connected. The central controllers 10a, 10b include detecting circuits 90a, 90b detecting a system failure impossible for **program** control and are connected with an emergency control circuit 30. **Programs** with the less number of times of usage are stored in the cartridge magnetic tape **devices** 60a(60b), and **backup** files are stored in the **device** 60a or 60b to unify the external **storage device** .

ABSTRACT

PURPOSE: To prevent a runaway of a microprogram when the contents of stand-by information are destroyed, by checking on the propriety of the contents of stand-by hardware information.

CONSTITUTION: When a restarting indication is made during page fault processing, the control **storage address** 12 of stand-by information, and the starting address 15 and ending address 16 of, for example, an instruction control microprogram stored in a starting address register 28 and an ending address register 29 are supplied to a comparison part 31 for a comparison. When a wrong branch to a module other than the instruction control microprogram is to occur as a result of the comparison, an address invalid signal 14 is set to 1 and a fixed address 17 from a fixed address register 30 is set in a control **storage address** register 25 as a substitute for the control **storage address** 12 of the stand-by information. When a **program** for stopping the system is set previously in the area of a control storage **device** 20 which starts at the address 17, the system is prevented from being shut down owing to a runaway of the microprogram.

ABSTRACT

PURPOSE: To reduce the load of **software** and promote speed-up of processing by **retrieving** the **address storage** section of a rear bus, finding out the corresponding rear bus address and executing again input/output access with the address.

CONSTITUTION: When there is a request for starting input/output (I/O) operation from a CPU1-2, a controller for interruption 7 decodes the bus address of an assigned I/O **device** , transfers this I/O request through a section controlling channel interface 11 to the channel of a channel unit and starts I/O operation. In this case, if the channel **device** is put into operation and busy or an unusable state due to trouble, then, the CPU1

retrieves the address storage section in the rear bus 14, finds out the corresponding rear bus address, and executes again the I/O access with the address.

Abstract (Basic): US 20030236933 A1

NOVELTY - A receiver receives the backup data from personal digital assistant (PDA), after deciding the start of automatic backup using decision unit. A storage unit (4) stores the received backup data, when a detector detects the establishment of connection between personal computer (PC) and PDA.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- (1) information equipment;
- (2) information processing system;
- (3) automatic data backup method;
- (4) data transmission method;
- (5) data reception method;
- (6) computer-readable automatic data backup program ;
- (7) computer-readable data transmission program ;
- (8) computer-readable data reception program ;
- (9) computer-readable recorded medium storing data reception program .

USE - Information processor e.g. PC for transmitting text data ,

backup data and image **data** to **information** equipment (claimed)
e.g. PDA.

ADVANTAGE - Useless automatic **data backup** operation is prevented by deciding the start of automatic **backup** operation. The **information** processing apparatus transmits the received **data** quickly and correctly.

DESCRIPTION OF DRAWING(S) - The figure shows the block diagram illustrating connection between **information** processing apparatus and personal digital assistant.

---------------	---	--	----	-------------	--

Abstract (Basic): US 20030182301 A1

NOVELTY - The method involves creating a baseline snapshot of a file system on a **backup** server and waiting for a predetermined period of time. An incremental restore is performed to the **backup** server. A new snapshot of the **backup** server is created. A number of snapshots

are managed according to a user-defined schedule by deleting one or more snapshots.

DETAILED DESCRIPTION - The baseline snapshot is created by performing a baseline dump of a file system associated with a **backup** client. The baseline dump is piped to a baseline file system on the **backup** server. A snapshot of the baseline file system is created on the **backup** server.

INDEPENDENT CLAIMS are also included for the following:

(a) a **backup** server operatively interconnected with a **backup** client

(b) a computer-readable **medium**, including **program** instructions executing on a **backup** server for managing many snapshots.

USE - Used in **storage** file systems for managing **backup** of **data** for **data** protection and restoration.

ADVANTAGE - The method allows the generation of snapshots of file systems, which do not inherently contain the capability to generate a snapshot. The method enables a reliable, fast and low-overhead tapeless **backup** using a remote destination **backup** file server.

DESCRIPTION OF DRAWING(S) - The drawing shows a schematic block diagram of a **storage** file system.

Abstract (Basic): EP 1349068 A2

NOVELTY - **Data** stored on a host system is read and a **data** profile is generated based on the read **data**. The **data** profile characterizes the **data** stored on the host system, which is also sent to a **backup** system. The **data** that need not be obtained from the host system, is determined based on the **data** profile.

DETAILED DESCRIPTION - INDEPENDENT CLAIMs are also included for the following:

- (1) A system for creating/updating a **backup** volume; and
- (2) A computer readable **storage medium** containing **program** for creating/updating.

USE - For **backup** system.

ADVANTAGE - The number of **data** blocks that need to be obtained from host system can be reduced.

DESCRIPTION OF DRAWING(S) - The figure depicts an exemplary process of creating/updating a **backup** volume.

Abstract (Basic): EP 1333379 A2

NOVELTY - The downloading of **data** into a **backup storage device** is done in duty cycles having a **backup** window period and an idle period. The **data** stored during **backup** window period is **retrieved** and compressed during the idle period. Space is reclaimed on the **storage device** by re-storing **data** in compressed form on the **backup storage device**.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for a **backup** apparatus.

USE - For **backup storage devices** like **backup** tape drive.

ADVANTAGE - Since the compression occurs when **backup device** is idle the rate at which **data** is backed up is not adversely effected in any way, thus low cost **software data** compression algorithm is used.

DESCRIPTION OF DRAWING(S) - The figure shows the flow diagram of a **backup** and compression duty cycle of the tape drive.

AU 2002318977 A1 G06F-013/00 Based on patent WO 200325760

Abstract (Basic): WO 200325760 A1

NOVELTY - The method for preserving electronic **data** , which is created in a generating location having a line connection to an offsite recording location, involves recording the **data** in an offsite location in a form, which is capable of recreating the **data** in the event of loss or corruption of the original.

DETAILED DESCRIPTION - Electronic **data** generated at a generating location e.g. a workplace, is sent by line connection to an offsite recording location from which it is **retrievable** in the event of loss or corruption of the material. The generated **data** is stored online in an intermediate **device** at the generated location and is released offline to a recorder at the offsite recording location via the line connection at a suitable rate. An intermediate recorder at the workplace collects **data** during working hours, encrypts the **data** and sends it offline to a local safe location via a telephone line. The **data** may be stored as discs or tapes in a vault.

USE - Electronic **data storage** and **retrieval** for preserving **data** at offsite location in event of loss or corruption of original **data** .

ADVANTAGE - System works on standard platforms and does not require specialized **software** . Internet independent.

DESCRIPTION OF DRAWING(S) - The drawing shows a schematic diagram of the locations.

Abstract (Basic): US 20020184243 A1

NOVELTY - A controller controls the switching of a host computer based on the system administration **information** corresponding to switching, storing of **data** and location of host computer. The transcription manager communicates the switching **information** to the computers connected to a network.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

- (1) database management method; and
- (2) computer-readable **medium** storing database management **program**

USE - For real time monitoring, controlling of **data** shared by computers distributed over a network such as Internet, intranet, etc. Also used for transaction management and distributed system administration for **backup**, recovery from faults and load distribution.

ADVANTAGE - As the host computer switching **information** is transmitted to several computers, system integration is easy and highly flexible to functional modifications. Allows easy execution of different types of settings. Enables quick system recovery during the failure of the host computer.

DESCRIPTION OF DRAWING(S) - The figure shows the block diagram of the database management apparatus provided in the host computer.

Abstract (Basic): US 20020156983 A1

NOVELTY - The contents of a cache memory are written into a non-volatile random access memory connected to the cache memory, when a power interruption is detected. On resumption of power supply, the contents are written back to the cache memory.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

- (1) Write back cache managing apparatus;
- (2) Hard disk drive;
- (3) **Data storage device** controller; and
- (4) Computer **program** product for implementing write back cache management method.

USE - For managing write back cache in computer.

ADVANTAGE - The contents of the cache are written into the non-volatile memory quickly by providing the non-volatile memory, the **data** loss during interruption of power supply is avoided and the reliability of cache operation is improved.

DESCRIPTION OF DRAWING(S) - The figure shows the flowchart explaining the cache **backup** operation.

Abstract (Basic): WO 2003009620 A1

NOVELTY - Method consists in using a user-carried **backup device** (BD) (20) having a memory and wireless communication (Bluetooth) link (WCL) of 10m or less for communicating with the portable **data storage device** (PDS) (10). Communication is made periodically between the BD and PDS over the WCL to **backup data** entered in the PDS and check for removal of the **device**, and an alarm (30) alerts the user to loss of the PDS if it is out of communication range for a given period.

DETAILED DESCRIPTION - There are INDEPENDENT CLAIMS for:

(1) A computer **program** for preventing **data** loss in a portable **device**

(2) A SIM card update

(3) A portable **data storage device**

(4) A **backup device**

(5) An **application** for a portable **data storage device**

(6) A mobile telephone

(7) An **application** for an article of smart clothing

(8) A method of securing a mobile telecommunications **device**

USE - Method is for mobile phones and PDAs.

ADVANTAGE - Method avoids the need for regular manual **backup**.

DESCRIPTION OF DRAWING(S) - The figure shows a system portable **data storage device** (10)

backup device (20)

alarm (30)

AU 2002346066 A1 G06F-017/30 Based on patent WO 200305247

Abstract (Basic): WO 2003005247 A2

NOVELTY - System comprises **storage devices** (SDs), a primary server (PS) granting or denying a global lock (GL) to **devices** requesting access to the **storage devices**, and secondary servers (SSs) with internal tables of **information**. The SS requests a GL from the PS and when it is granted the SS checks its tables to determine whether access to the SD can be granted and marks the SD portion as locked. It sends the **information** to the PS and SSs for **storage** in their tables. A network connects the SD, PS and SSs.

DETAILED DESCRIPTION - There are INDEPENDENT CLAIMS for:

- (1) A method of granting and denying access to servers in a network
- (2) A computer **program** for granting and denying access to servers in a network

USE - System is for backing up files, databases etc. on servers and other network machines.

ADVANTAGE - System enables the server to be freed up during **information backup**.

DESCRIPTION OF DRAWING(S) - The figure shows a LAN environment.

Based on patent WO 200305158

Abstract (Basic): WO 2003005158 A2

NOVELTY - System comprises a **storage** (tape) **device** and a controller including a scheduling system for allowing a user to input into a job queue, the master job indicating the portions of the **information** to be backed up or restored. A job control system splits the master job into smaller jobs for **backup** or restore of a single source entity for input into the job queue. The user specifies the time for the master job to run and a job engine periodically scans the queue for jobs to be run.

DETAILED DESCRIPTION - There are INDEPENDENT CLAIMS for:

(1) A method of backing up and restoring **information** on a computer system

(2) A computer **program** for backing up and restoring **information**
USE - System is for backing up files, databases etc. on servers and
other network machines.

ADVANTAGE - System enables the server to be freed up during
information backup .

DESCRIPTION OF DRAWING(S) - The figure shows a LAN environment.

Abstract (Basic): EP 1246064 A2

NOVELTY - A computer storing original **data** piece of a database is
designated as base host and another computer storing replica **data** of
the original **data** is designated as replica host. A **retrieval**
procedure is performed to receive **data** from the base host or replica
host and store in another computer.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the
following:

(1) Computer readable **medium** storing real-time database
management **program** ;

(2) Real-time database management system; and

(3) Carrier **medium** for real-time database management.

USE - For managing database in real-time.

ADVANTAGE - Allows addition of databases to a system without
bringing the entire system to a halt by using the base and replica
hosts, and also achieves accurate control of initial **data** loading for
enhancing online system.

DESCRIPTION OF DRAWING(S) - The figure shows the functional block diagram of the real-time distributed database management system.

Abstract (Basic): GB 2368161 A

NOVELTY - A controller (122) is switched to a write through cache mode, when a predetermined controller (120) is failed and replaced. The controllers (120,122) are operated in write back cache mode, when the state **information** of battery **backup** for both controllers reaches a predetermined value.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

(1) Disk drive array system; and
(2) Article of manufacture comprising **program storage medium** storing controller operating **program** .

USE - For use in disk drive array system (claimed).

ADVANTAGE - **Data** is protected and controller waiting period is shortened by enabling cooperation between replacement and survivor controllers to start write back cache operation immediately.

DESCRIPTION OF DRAWING(S) - The figures show block diagram of disk drive array system and flowchart illustrating the steps for failed controller replacement.

Controllers (120,122)

pp; 23 DwgNo 1, 3/3

Abstract (Basic): WO 200221273 A2

NOVELTY - A self-archiving log structured volume (16) copies blocks from random access digital medium (18) to archival digital medium (20) during execution of storage application (14). An agent indicates the structured volume about correspondence between the blocks and the application. Both the mediums store logged blocks and synchronous events of the structured volume.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for data back - up method.

USE - For **data back - up** in computer network.

ADVANTAGE - **Data** is protected soon after it is written and all versions of a **data** object are recoverable. Since **data** protection does not depend on operator action, **data** recovery is fast, easy and reliable.

DESCRIPTION OF DRAWING(S) - The figure shows the block diagram of the self-protecting **data back - up** system.

Storage application (14)

Self-archiving log structure volume (16)

Random access digital **medium** (18)

Archival digital **medium** (20)

Patent No	Kind	Lan	Pg	Main IPC	Filing Notes
US 6353878	B1		33	G06F-011/14	

Abstract (Basic): US 6353878 B1

NOVELTY - A **backup media** remote control command corresponding to the **backup media** remote control request, is sent from primary **data storage** subsystem to secondary **data storage** system, as received from a host processor. The tape library unit (70) in secondary **storage** system stores a directory of versions of **backup data** , after execution of the **backup media** remote control.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

(a) A **data storage** system;

(b) A machine readable **program storage device** containing a **program** executable by a **storage controller** of a **data storage** subsystem

USE - Used in computer network for **data storage backup** more particularly to remote control of secondary **storage** subsystem through a primary **storage** subsystem.

ADVANTAGE - **Backup** and restore services reduce the impact of

data loss from the network **storage** . **Data** stored on a network is saved from severe failure of **data storage** system.

DESCRIPTION OF DRAWING(S) - The figure shows the block diagram of **data** processing system.

Tape library unit (70)

JP 2003526156 W 34 G06F-003/06 Based on patent WO 200167247

Abstract (Basic): WO 200167247 A1

NOVELTY - The Peer to Peer Remote Copy (PPRC) **backup** system maintains a simultaneous copy of the **data** at a second remote site. During a **data** write operation, the primary **storage** (304) is updated by the **application** . Once complete a snapshot copy of the **data** is passed to the primary bridge **storage** (316). This is then relayed over

the network to the secondary bridge volume (320) which updates the secondary **storage device** (310).

DETAILED DESCRIPTION - On completion of the **data** update, the secondary bridge **storage** volume passes a completion message through the second status volume (326) over the network to the primary status volume (318) which de-queues the transfer and in turn updates the primary **storage** volumes.

An INDEPENDENT CLAIM is also included for a **data** processing system using the **data** transfer method.

USE - To provide a peer to peer remote copy (PPRC) **data backup** system.

ADVANTAGE - As the **data** being backed up is first snapshot copied to the primary **storage** volume, the **application** receives a write acknowledgement without incurring the network latency of the previous system, in effect the **backup** task is handed off to the primary bridge **storage** volume.

DESCRIPTION OF DRAWING(S) - The drawing shows a block diagram of the **backup** system.

primary **storage** (304)
secondary **storage device** (310)
primary bridge **storage** (316)
primary status volume (318)
secondary bridge volume (320)
second status volume (326)

Abstract (Basic): EP 1143338 A1

NOVELTY - Connections (VA,VBA1,VBA2) are established between a
data processing device (TERA) and corresponding remote **back - up**
servers (BA1,BA2) through a telecommunication network (NET). **Data**
streams containing **back - up data** are transmitted from processing
device to corresponding **back - up** servers, through the network
(NET).

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the
following:

- (a) **Data processing device** ;
 - (b) **Program** module for **data processing device** ;
 - (c) **Data back - up** service provision server;
 - (d) **Back - up** server;
 - (e) **Program** module for service provision server;
 - (f) **Program** module for **back - up** server;
 - (g) **Storage medium** e.g. floppy disc in which **program** modules
for **data processing device** and **back - up** server are stored
- USE - For backing-up **data** of **data processing device** (claimed)
such as personal computer connected to telecommunication network e.g.
telephone network, broadband network, internet or any other combination
of different networks suitable for **data** transmission. Is also
applicable in telecommunication **information** networking architecture.

ADVANTAGE - Since **back - up data** is stored in different remote
back - up servers, **data** loss is eliminated and unauthorized access
of **back - up data** is reduced.

DESCRIPTION OF DRAWING(S) - The figure shows an explanatory drawing
of **data back - up** process.

Remote **back - up** servers (BA1,BA2)
Telecommunication network (NET)
Data processing device (TERA)
Connections (VA,VBA1,VBA2)

Abstract (Basic): WO 200142922 A1

NOVELTY - A scalable **storage** architecture **storage** module includes IFS file systems for managing files where meta- **data** and **data** may be stored on multiple separate **devices** with different characteristics and comprises a kernel-space module (78) and a user space communication module (79), communicating through a shared memory interface (92), while a database server (82) stores file **information** and a virtualization demon (80) performs **data** removal from the primary **media** . **Information** is **retrieved** on request by secondary **storage** units (86) from the file system and a repack server (84) efficiently packs **data** on the **storage devices** .

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for methods for robustly storing **data** , for managing **storage** space and for accessing a historic **storage** .

USE - **Data storage** and **retrieval** .

ADVANTAGE - Providing integrated **storage** solution.

DESCRIPTION OF DRAWING(S) - The drawing is a block diagram of **storage control software**

Kernel and user communication modules (78,79)
Database server (82)
Virtualization demon (80)
Secondary **storage** units (86)
Repack server (84)

Abstract (Basic): EP 1091299 A2

NOVELTY - Record of historic states of disk having X,Y and Z disk locations are created. New **data** is stored to disk location Y in response to request to overwrite original **data** at disk location X. An indication indicating roles of disk location X and Y is established. Command to release **data** at disk location Z is intercepted and

indication indicating disk location Z storing historic **data** is established in record.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

(a) Computer **program** ;

(b) Computer readable **media** prior state restoration method

USE - For recovering **data** stored in digital computer disk of operating system.

ADVANTAGE - Allows reconstruction of prior state of a computer disk in a safe and chronologically controlled manner. Prior state of computer disk is reconstructed using both the current status of the disk and the historical **data** . Combines sector level backups with file **backup** levels to increase both efficiency and reliability. Allows the operating system to select actual **storage** location to write **data** to, while ensuring that old historic **data** that is required to recreate a prior state of disk is protected from the operating system. Supports defragmentation process and shape **data** transition to actual disk **media** .

DESCRIPTION OF DRAWING(S) - The figure shows the block diagram showing the initial system state.

Abstract (Basic): EP 1065585 A2

NOVELTY - A list of source and destination **storage** location **addresses** is established and these locations are then made immediately available to host **application** processes. The copying of data is then started in an orderly manner, e.g. files can be transferred on a track by track basis. The list is updated to indicate the status, and eventual completion, of the transfer. If an access request is received for a data block during copying, the orderly copying is suspended, the requested block is copied and the list is updated accordingly. The access is then serviced and orderly copying resumed.

USE - In data processing systems.

ADVANTAGE - Interruption of host **application** programs is minimized.

US 20020078078 A1 G06F-012/00 Cont of application WO 2000FI436

Abstract (Basic): WO 200077645 A1

NOVELTY - Predefined changes are made in central memory storing database only. In addition to most current version (D') of mature generation of database stored on disk, previous version (D) stored on disk are maintained in disk memory. Recovery of database is performed by reconstructing remembered set of previous version and by changing **pointers** indicated by that set to refer to memory cell of most current version.

DETAILED DESCRIPTION - The database comprising primary generation and mature generations is maintained in central memory. The generations contain memory cell in which **data** and additionally **pointers** constituting references between memory cell are stored. The generation-specific remembered sets are stored in the area of mature generations in the central memory in which addresses of the **pointers** pointing to each generation in question are listed. The memory is allocated for use of **application** from the area of the primary generation in central memory. The line memory cell in the primary generation area are collected as new mature generation into mature generations of the central memory. The garbage collection is performed in the area of mature generations. In connection with the collection, a remembered set is examined and line memory cell are copied in the order indicated by the remembered set into temporarily more recent mature generation. As the garbage collection proceeds, changes to the reference between generations are made in the area of mature generation, in generation that has already been stored in disk memory.

USE - For recovery of database provided with disk **back up**, in telephone exchange also for recovery of database used in the industrial process controls. Also for database recovery used in different **application** environments.

ADVANTAGE - Enables substantial reduction in writing onto disk required by **back up**, thus making the operation of database substantially more rapid than the conventional cases. Thereby memory space left for actual payload **data** can also be made substantially greater than conventional cases, since it is not necessary to store the remembered sets on disk at all. The central memory needs only the remembered sets in uncollected mature generations only. The generation remains the same during the entire garbage collection and thus it can be used in system in which more than one processor performs garbage collection in parallel.

DESCRIPTION OF DRAWING(S) - The figure shows flow chart illustrating the operation of recovery system.

Abstract (Basic): EP 1058190 A2

NOVELTY - The **data back - up** system obtains **back - up** of **data** stored in a **storage** system (1) comprising **storage** units, to a **back - up device** (3). The **storage** system (1) operates to transfer user **data** inside a secondary **storage** unit, to the **back - up device** (3) in response to a copy instruction.

DETAILED DESCRIPTION - A **storage** system (1) holds user **data** in two **storage** units. In backing up the user **data** , a split instruction for releasing the duplex state of the two **storage** units is sent from the host computer (2) to the **storage** unit. In response to the split instruction, the **storage** system (1) interrupts the reflection of the update of the user **data** to the first of the **storage** units onto the second **storage** unit. A copy instruction for copying the user **data** held in the second **storage** unit to the **back - up device** , is then sent from the host computer (2) to the **storage** system (1). The **storage** system (1) operates to transfer the user **data** inside the secondary **storage** unit, to the **back - up device** (3) in response to the copy instruction. INDEPENDENT CLAIMS are included for; a **back - up device** coupled with the computer; a **storage** system; a **back - up** method.

USE - Obtaining a **back - up** of the **data** stored in a **storage** unit to the **back - up** **device** .

ADVANTAGE - Enables backing-up of **data** from disc system into **storage medium** for **back - up** without having to interrupt I/O processing of an **application program** running on a computer. Enables backing up of **data** such that waiting time of writing process of the **application program** is reduced as reduction in the times of copies.

DESCRIPTION OF DRAWING(S) - The drawing shows a conceptual diagram showing a general concept of **back - up** processes according to a first embodiment of the invention.

Abstract (Basic): GB 2353611 A

NOVELTY - The filing system is used to identify files that need to be personalized in a first system, the system writes pre-defined signature **data** to the files and scans portions of backed **data** executed by BIOS functions for the signatures. Absence of a signature in the **storage** portion restores previously personalized files.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for a **data** processing system, a computer **program** product stored on a computer readable **medium**.

USE - For backing up **data**.

ADVANTAGE - The **data** is backed-up without access to the filing system and the areas of the original **medium** not used is not affected, some files can be easily personalized before the target operating system boots, and the system name/network addresses does not require changes to make the system unique on the network.

DESCRIPTION OF DRAWING(S) - The figure shows a flowchart of the second phase of the **backup program** for filing system.

Cont of patent US 6643667

Abstract (Basic): EP 1039387 A2

NOVELTY - To copy a logical volume of data, the data and a logical

address section is transferred to the buffer. The data is copied into a second section of buffer with the address section transformed from **physical address** of the first volume to **physical address** of the copy of that logical volume. The data is then copied from buffer to a storage **device** to form the copy of the logical volume independently of the data processing units and their channels.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for:

- (a) a computer **program** product for controlling the copying of information from a first logical volume to a second logical volume;
- (b) a control unit for controlling the copying of information; and
- (c) and a computer system.

USE - In data processing systems.

ADVANTAGE - Avoids occupying data processing units and host channels when copying data.

DESCRIPTION OF DRAWING(S) - The figure shows an illustration of simplified block diagram of a representative example computing system for copying data.

Abstract (Basic): WO 200058834 A1

NOVELTY - The initial bootstrap instructions initialize low-level parameters of client **device** and load bootstrap loader from persistent store into **program** memory (802). A second stage boot loader (806) locates OS in persistent store and loads it to **program** memory. The OS performs necessary hardware and **software** initialization and loads the viewing object database code and **application software** from persistent store.

DETAILED DESCRIPTION - The boot sector (804) contains sufficient **information** for initial bootstrap, to understand the partitioning of persistent store. The persistent store has two partitions containing a copy of second stage boot loader and OS kernel and a copy of **application software**. A partition table in the boot sector, is recorded with an indication for duplicated partitions which are marked as primary and **back - up**. INDEPENDENT CLAIMS are also included for the following:

- (a) an apparatus for installing and recovering **software** ;
- (b) a **program** product

USE - For maintaining distributed database of television viewing **information** among computer systems.

ADVANTAGE - Improves the ability of individual user to select and automatically time shift TV **programs** while providing opportunities for service provider to enhance and direct the viewing experience.

DESCRIPTION OF DRAWING(S) - The figure shows the block diagram of bootstrap system.

Program memory (802)
Boot sector (804)
Boot loader (806)

Abstract (Basic): EP 981090 A1

NOVELTY - The method involves dividing a base file into a series of segments. For each segment a segment description is generated. From the generated segment descriptions a segments description structure id created as the checkpoint.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for:

- (a) a method of producing a morph list that defines an updated version of base file with reference to the base file and check point
- (b) a method of generating a difference file defining differences between an updated file and a base file

USE - For producing a checkpoint, which describes a box file and a method of generating a difference file defining differences between an updated file and a base file. The invention can be applied for example to network systems where a remote copy of a file is kept up-to-date by the transmission and **application** of the differences between the successive versions of the local copy.

ADVANTAGE - Allows using bandwidth more efficiently, which includes modern on-line **backup** and **data** replication systems. Enable applications to transmit only the changes to memory-loaded files from client to server on successive save operations and can also be applied for example to **backup** subsystems, where storing only a difference to files can make more economical use of **storage media**.

DESCRIPTION OF DRAWING(S) - The drawing is a flowchart showing a series procedures embodying the invention.

Abstract (Basic): WO 9923562 A1

NOVELTY - Disk SMART system (210) monitors disk attributes by providing registers which are polled by BIOS/Driver (212) and used by **application** agent (214) to determine impending failure, and initiate tape (120) **backup** of **data** on disk drive (118). **Backup program** (222) can cause **backup** to any suitable **storage device** which can be remote. Polling interval can be user defined.

DETAILED DESCRIPTION - Disk attributes include: head flying height, spin-up time, reallocated sector count, seek error rate, seek time performance, spin try recount, and drive calibration retry count.

USE - Personal computers, portable computers, servers, midrange computers.

ADVANTAGE - Prevents loss of **data** when disk drive fails. Allows user to continue working or leave unattended.

DESCRIPTION OF DRAWING(S) - The drawing shows component parts of the invention.

Abstract (Basic): WO 9912098 A1

NOVELTY - In a network environment (200), multiple clients (210) and multiple servers (230) are connected via a local area network (LAN) (220) to a tape **back - up** apparatus (240). Each client (210) and each server is provided with **back - up** agent **software** (215), which schedules **back - up** operations on the basis of time since the last **back - up**, or the amount of **information** generated since the last **back - up**. An agent (215a) also sends a request to the tape **back - up** apparatus prior to the actual **back - up**, including **information** representing the files that it intends to **back up**.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for; a method for backing up to a **data back - up** and restore apparatus attached to a network; a **data storage** system; and a **data back - up** and restore apparatus.

USE - **Data back - up** and recovery in tape **storage** system in computer networks.

ADVANTAGE - Clients do not need to send redundant files for **back - up**.

DESCRIPTION OF DRAWING(S) - The drawing shows a diagram of a computer network modified in accordance with the invention.

Abstract (Basic): WO 9848347 A

When an **application program** requests a **backup** or copy of a selected **device**, the MVS (Multiple Virtual **Storage**) **device backup** system determines the source **device** volume and the destination (target) **device** volume on the **data storage** subsystem, in order to identify the extents of both.

The **backup** system then transmits **data** to the **data storage** system, representing the assignment of DASD (Direct Access **Storage Device**) full tracks from the source **device** location on the **data storage** subsystem, as well as DASD full tracks from the target **device** location on the **data storage** subsystem.

The **backup** system then uses ECAM (Extended Channel Access Method) channel **programs** to instruct the **data storage** subsystem to perform a **backup** operation using the **data storage** subsystem snapshot track **pointer** copy operations.

ADVANTAGE - Minimises the use of **data** processor resources, as the processor is not used to perform the movement of **device data** during the **backup** operation.

Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
JP 10260854	A	11	G06F-011/14	

Abstract (Basic): JP 10260854 A

The system has a CPU (12) with a main memory (13) by which the state **information** of a peripheral **device** (6) is assigned to a **back - up** memory mapping area. The I/O instruction from the CPU is developed to an instruction based on each peripheral **device** , and sent to the peripheral **devices** .

A peripheral **device** controller receives the I/O result of normal or abnormal degree from the peripheral **devices** . A **back - up** memory (21) with same area section as the main memory used for the operation of an **application** , is connected to the CPU and the peripheral **device** controller via a common bus. The **back - up** memory preserves the state of each peripheral **device** .

ADVANTAGE - Improves reliability since state of peripheral **devices** are preserved. Minimises processing time during abnormal operation of system and reduces processing time of peripheral **devices** using flash memory during abnormalities. Prevents malfunction of **application** caused by inaccurate state **information** of peripheral **devices** since state **information** is held.

GB 2310059	B			G06F-011/14	

Abstract (Basic): GB 2310059 A

The computer has two non-volatile, re-writable storage devices i.e. a hard disk drive or HDD and the other has a semiconductor-based battery buffered RAM which contains at least some of the data files which can be called up and written by the programme of the computer. Continuously arising data are written by the computer into the data files contained in the battery buffered RAM.

From time to time the data files contained in the battery buffered RAM are backed up on to the hard disk drive. During the access-free time the read-write head of the HDD is moved across regions or cylinders of the drive, so that any head crashes are not concentrated in one region of the disk, and so the disk may be tested.

ADVANTAGE - More effective protection against loss of data arising at short time intervals, esp. w.r.t. detection and storage of machine rhythm dependent data having corresp. frequent accesses to same regions of tracks and cylinders of drive at which head is positioned - i.e. data losses caused by disk crashes can be minimised, esp. of data arising from the capture and recording of data which arise at a rate dependent upon printing speed, e.g. counter state of printer sheet counter.

US 6405294	B1			G06F-013/14	
------------	----	--	--	-------------	--

Abstract (Basic): WO 9724669 A

The method involves verifying **data** integrity on source DASD (104), and initiates processes to mirror volumes of **data** from source DASD to target DASD, and to mirror **data** updates to volumes of **data** by the applications of the source mainframe to the target DASD. The **data** updates are synchronised to the volumes by the source mainframe applications with corresponding **data** updates to the target DASD.

The source mainframe (102) applications are deactivated, and the remaining **data** updates are mirrored to the target DASD (124). The source **data** centre is disconnected from the target **data** centre. The target **data** centre is brought on line and the target mainframe (122) applications are initiated.

ADVANTAGE - **Application** downtime is greatly reduced. No **backup** to tape, transportation or restore to target system is needed, giving customer **application** down time of sixty minutes during which processing is transferred from one **data** centre to another.

US 5907672	A			G06F-011/16	
------------	---	--	--	-------------	--

Abstract (Basic): EP 767431 A

The method reads a set of logically contiguous sectors from the primary store using an OS **software** call providing access to files on the primary store, it performs any physical remapping necessary to avoid previously detected physical flaws on the primary store. The set of sectors are written to the **backup** store, such as magnetic tape. A partition is created on the restore store of a size as large as the size of the primary store.

A set of logically contiguous sectors is read from a location on from the **backup** , and written to the partition of the restore store using a **software** call to the OS that provides access to the files stored on the partition. The call performs any physical level remapping as before for the restore store.

USE/ADVANTAGE - For backing up **data** at high speed from a computer disk volume onto **backup medium** and subsequently restoring some or all **data** in event of **data** loss or corruption. Allows high speed tape **devices** to stream during **backup** process, without forcing user to accept compromises in flexibility or performance of restore process.

Abstract (Basic): GB 2298940 A

The **data backup /restore device** (1), which is not itself a computer workstation or file server, is provided for backing up and restoring **data** supplied over a local area network (3) comprising computer workstations and a file server interconnected by a network connection. The **device** (1) comprises a **data storage device** (2), a **storage device** controller (4), a decoder-encoder (8) and a LAN interface (9) for connection to the network connection separately from a computer workstation or file server, and a LAN co-processor (6) for transferring **data** between the **data storage device** (2) and the computer workstation.

The **data back - up** or restore **device** (1) can be connected to the local area network (3) at a location remote from any computer workstation or file server within the network.

ADVANTAGE - Performs **data back - up** and restore operations and **data** interchange with any computer workstation or file server without need for direct connection to computer workstation or file server and without need to load and run any **software** on file server. Avoids fitting of extra interface boards within personal computer. No **software** module is resident on file server.

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
JP 8087310	A	9	G05B-019/05	

Abstract (Basic): JP 8087310 A

The programmable controller carries out execution of an instruction input at a certain scanning period. In case of error generation, a retry processing unit (42) comprising an error retry processing function, performs execution of a instruction for a number of times until the error is eliminated.

If error is not eliminated, then the concerned scanning period is terminated by a scanning period end unit (44), thereby storing the error generated address in a storage unit (52). Finally, the execution of the program is stopped by an execution stop unit (43).

ADVANTAGE - Improves error retry processing of input access.

Abstract (Basic): EP 650122 A

The **backup** system operates with **data** stored in file format on local bulk memory in individual computers. The stored **data** is read (11) and files modified since the last **backup** identified. Altered files are enciphered (15) and compressed (31) before transmission over an ISDN communication link (1).

When the **data** is received at a central **data storage** it is automatically numbered under control of the processor of the central **storage** computer.

USE/ADVANTAGE Centralised **backup** of **data** held on personal computers. Easily used, reliable and secure system.

Abstract (Basic): GB 2281986 A

The appts includes an instruction decoder for decoding instruction code words, a **program** counter for indicating an instruction address of an instruction code word to be decoded. A reset circuit is responsive to a reset signal for triggering resetting of the appts.

A **program** counter storage **device** is responsive to reset signal for storing a latest instruction address from the **program** counter prior to occurrence of reset signal. The appts further includes a number of data registers for holding data to be manipulated, which are cleared as result of the reset signal.

USE/ADVANTAGE - In recovery of system after malfunction or crash, partic during hardware and **software** development. Exclusion locking of processor.

Abstract (Basic): EP 566966 A

The data processing method involves suspending **application** execution within data processing system at a first point in time. Forming a dataset logical to physical **storage** system **address** concordance for the designated datasets and resuming **application** execution thereafter.

Physically backing up the datasets within one or more storage subsystems on a scheduled or opportunistic basis by copying the datasets from one storage subsystem to alternate storage subsystem locations. Storing an indication of each initiated **application** update to the datasets which occurs after the first point in time.

ADVANTAGE - Provides an improved method and system for maintaining continued availability of datasets in external storage associated with accessing data processing systems.

Abstract (Basic): US 5241669 A

The method involves forming a data set logical-to- **physical** system **address** concordance for the designated data sets to be utilised to administer copying of the designated data sets. Any **application** initiated update is processed at the storage subsystem to uncopied portions of the designated data sets by temporarily deferring the updates, writing sidefiles of the designated data sets or portions thereof affected by the update to the subsystem memory and thereafter writing the updates to the storage subsystem.

The designated data sets are accessed and copied within the storage subsystem on a scheduled or opportunistic basis by issuing data retrieval command sequences from the data processing system to the storage subsystems. A side file status query is periodically appended to a data retrieval command sequence wherein a determination of data presence within the subsystem memory may be accomplished. The side files are selectively accessed and copied in response to a determination of data presence within the subsystem memory.

ADVANTAGE - Provides enhanced efficiency of backup copying of designated data sets.

Patent Details:

Patent No	Kind	Lan	Pg	Main IPC	Filing Notes
US 5241668	A		13	G06F-013/20	
EP 566965	A2 E	14		G06F-011/14	
Designated States (Regional): DE FR GB					
EP 566965	A3			G06F-013/20	
US 37038	E			H03K-019/003	Reissue of patent US 5241668

Abstract (Basic): US 5241668 A

The method involves entering a status indication into activity tables associated with **storage** subsystems and **devices** within a **data** processing system in response to initiation of a **backup** copy session. Status indications are then entered upon successful completion of a **backup** copy session within the **data** processing system. The indications within the activity tables are reviewed to determine the status of a **backup** copy session upon restarting a resource manager, abnormal termination of a **backup** copy program, or an operating system initial program load. If a **backup** copy session has been initiated but not completed, the **backup** copy session is then terminated. The indications within the activity tables are also reviewed to determine the status of a **backup** copy session if a reset notification is raised by a **storage** subsystem. The tracks extends which are active for a volume associated with a particular session identification are determined.

A comparison is then made between the tracks extends which are active and the volume and extent **information** associated with a

physical session identification. If a match exists between the tracks extends which are active and the volume and extent **information** associated with a physical session identification, the **backup** copy session resumes. If a match does not exist, the **backup** copy session is terminated.

ADVANTAGE - Provides copying of records in external **storage** concurrent with dramatically shortened suspension of **data** processing system **application** execution occasioned by copying

KR 9514175	B1			G06F-012/00	

Abstract (Basic): WO 9308529 A

The back-up method is concurrent with CPU **application** execution. It involves suspending **application** execution and forming a data set

logical-to-physical storage sub-system address concordance and resuming execution thereafter. The data sets are backed-up on a scheduled or opportunistic basis.

At the storage sub-system any **application** initiated updates are processed to uncopied data sets. Side files of update dataset portions are written to storage in the concordance defined back-up copy order.

ADVANTAGE - Reduced suspension time of CPU **application** execution.

Abstract (Basic): EP 433979 A

An error is detected in one of the CPUs which is then isolated from the system. Execution of the instruction stream is continued and the global memory units are accessed by other CPUs. The isolated CPU is reintegrated after being rendered operative by first bringing it into sync with the other CPUs, then restoring the state and local memory of the CPU to be identical to the others.

USE - Detection and reintegration of faulty components, and shutdown and restart procedure in event of power failure. (2pp Dwg.No.1/16)

Abstract (Basic): WO 9101026 A

The method of operating a **data** processing system includes a random access memory a central processing unit and a non-volatile **storage device** , in which the central processing unit, operating according to instructions stored in the memory, is caused to write **data** periodically to basic **storage** forming at least part of the **storage device** .

For a set of such write operations the central processing unit is caused by the instructions to execute a set of corresponding **backup** write operations to write the same **data** to **backup storage** .

ADVANTAGE - Normal use of computer substantially unaffected by **backup** process, restore process avoids bad sectors of destination **storage** . (25pp Dwg.No.1/5)

Abstract (Basic): GB 2234373 A

A method of operating a **data** processing system, in particular a micro-computer, comprises a **backup** process in which a copy of every change made to a **storage medium** is recorded as the change occurs. Write operations for writing **data** to the **storage medium** are each preceded by a **backup** write operation to **backup storage** means, successive **backup** write operations being controlled so as to be stored as a sequential list in the backups **storage** means in the form of location blocks and **data** blocks to avoid the overwriting occurring in the **storage medium**.

These **backup** write operations are executed at the level of the basic input/output system (BIOS) of the microcomputer in such a manner that normal use of the computer is unaffected. The method also includes a restore process in which bad sectors of a destination **storage device** are avoided by translating the file allocation table (FAT) and directories of the original **data**.

USE/ADVANTAGE - Providing copies of **data** stored in **storage devices** to guard against possibility of **storage device** becoming faulty or **data** becoming corrupted, lost or infected by computer virus. Especially concerned with provision of backups for personal computers. (15pp Dwg.No.4/5)

Title Terms: **STORAGE** ; BACK; UP; SYSTEM; PERSON; COMPUTER; WRITING; **DATA** ; PERIOD; BACK; UP; **STORAGE** ; SEQUENCE; WRITING; OPERATE; **SOFTWARE** ; ROUTINE

Abstract (Basic): EP 393631 A

A start processing system after cutoff of a power source of the present includes a read-only memory (ROM) for storing a **program** for executing the initial processing, a **program** for executing the main processing and for storing initial **data**, a random access memory (RAM) for storing and reading **data** when the main processing is executed and a **backup device** for keeping driving of the RAM for a predetermined time after cutoff of the power source.

The **program** for executing the initial start **program** includes a **program** for comparing **data** stored at a predetermined address area of the RAM memory with **data** stored at a predetermined address area of the ROM and for moving the initial **data** stored in the ROM to the RAM when the result of comparison of the **data** proves different.

USE - A system using a processor or microprocessor for executing a predetermined initial processing and then a main processing based on a predetermined **program** when a reset signal is inputted.

Abstract (Basic): WO 8903558 A

The automatic **back up** proceeds in the following stages: the **data** to be saved is predetermined and stored. The **application program** is made to incorporate **software** for detection and execution of the request to save the **data**. A save initiation signal is generated at the computer interface port to initiate the automatic **back - up**, the **data** being stored on a reliable **storage medium**.

The interface ports (9,10) of the computer are linked to the port (8) of an external electronic **back - up** controller (4) which monitors the computer port for a **back - up** initiate signal and delivers a start signal to the **storage device** when **back - up** is required.

USE/ADVANTAGE - Provides automatic **back - up** of hard discs in computer installations onto tape streamer or printer, increasing **data** safety.

Abstract (Basic): EP 297893 A

A vector restart frame for recovery from a page fault includes a signal group (401) with all logic zeros except for the first three bit positions. These positions identify an access violation, a fault or read, a fault on write, translation invalid or vector alignment and instruction pending. The vector length or number of **data** elements involved is designated in a further signal group (402). The initial base address (403), stride or displacement (404) between successive **data** elements, and the related virtual address (405) in the page of the missing **data** element causing the exception are designated in respective signal groups.

The vector load or store instruction which prompted the exception is signalled in a further group (406) and the processor status in a yet further group (407). In the status group the field of bit position two (VRF) is of particular significance in indicating that a previous vector restart frame has been saved. The virtual address of the next instruction provides the final group (408) of the frame.

ADVANTAGE - Overlapping vector and scalar operation instructions can be executed

Abstract (Basic): EP 292791 A

A virtual memory management unit (34) translates a virtual address described in the instruction into a **physical address** of the main memory (50), coupled with it and the cache memory (36) to a 32-bit BP bus (32). A register file (2) is coupled to a stack for storing the low-order portion of an operand address, and to a memory unit generating an interrupt if the operand is not stored therein.

The control store (38) responds with an alternative control signal sequence following such an interrupt, and to a carry signal from an arithmetic unit (4) with a sequence reinstating the unmodified memory address.

USE/ADVANTAGE - In data processing system using virtual memory address scheme. Improved throughput is safeguarded without performance degradation incurred in exclusively firmware operation.

Abstract (Basic): EP 272821 A

The calculator provides an operator stock which stores operators sequentially, and a **data** stock which stores **data** sequentially. The calculating system is coupled to the stocks and arranged for performing calculations using the operators stored on the operator stock and the **data** stored on the **data** stock. A replication of the operators of the sequence of operators stored on the operator stock is stored on the operator **back - up** stock. Similarly for **data**, a **back - up data** stock is provided.

In response to actuation of the UNDO key the contents of the operator stock end of the **data** stock are exchanged with those of the operator **back - up** stock and the **data back - up** stock.

ADVANTAGE -Can recover from accidental or incorrect key actuation or command execution, operator is not required to re-enter all arguments for each operation.

Abstract (Basic): EP 105710 A

The unit includes a control storage for microinstructions. A control register stores an address for specifying the microinstruction and microinstruction register as tags. The two registers are in multistage connection. An error detection and correction circuit checks the validity of each microinstruction. A retry operation is performed for the related microinstructions including the detected erroneous microinstruction under an interlock mode, in which the erroneous microinstruction and the related preceding microinstructions are successively subjected to error detection and correction.

This is followed by re-execution, recording an address specifying the erroneous microinstruction. An interlock mode operation is performed for only the erroneous microinstruction when the address is again accessed. The interlock mode is created by doubling one of the steps defined by a machine cycle of the unit. This enables recovery in short time.
